Lab 14

Financial Risk System

Background
A global investment bank based in London, New York and Singapore trades (buys and sells) financial products with other banks (counterparties). When share prices on the stock markets move up or down, the bank either makes money or loses it. At the end of the working day, the bank needs to gain a view of how much risk they are exposed to (e.g. of losing money) by running some calculations on the data held about their trades. The bank has an existing Trade Data System (TDS) and Reference Data System (RDS) but need a new Risk System.

Trade Data System
The Trade Data System maintains a store of all trades made by the bank. It is already configured
to generate a file-based XML export of trade data at the close of business (5pm) in New York.
The export includes the following information for every trade made by the bank:
• Trade ID
• Date
• Current trade value in US dollars
• Counterparty ID

Reference Data System
The Reference Data System maintains all of the reference data needed by the bank. This includes information about counterparties; each of which represents an individual, a bank, etc. A filebased XML export is also available and includes basic information about each counterparty. A new organization-wide reference data system is due for completion in the next 3 months, with the current system eventually being decommissioned.

Functional Requirements
The high-level functional requirements for the new Risk System are as follows.
1. Import trade data from the Trade Data System.
2. Import counterparty data from the Reference Data System.
3. Join the two sets of data together, enriching the trade data with information about the counterparty.
4. For each counterparty, calculate the risk that the bank is exposed to.
5. Generate a report that can be imported into Microsoft Excel containing the risk figures for all counterparties known by the bank.
6. Distribute the report to the business users before the start of the next trading day (9am) in Singapore.
7. Provide a way for a subset of the business users to configure and maintain the external parameters used by the risk calculations.

Additional Requirements
• The system must be able to cope with trade volumes for the next 5 years.
• The Trade Data System export includes approximately 5000 trades now and it is anticipated that there will be an additional 10 trades per day.
• The Reference Data System counterparty export includes approximately 20,000 counterparties and growth will be negligible.
• There are 40-50 business users around the world that need access to the report.
• Risk reports basically should be available to users 24x7, but a small amount of downtime (less than 30 minutes per day) can be tolerated.
• This system must follow bank policy that states system access is restricted to authenticated and authorized users only.
• Reports must only be distributed to authorized users.
• Only a subset of the authorized users are permitted to modify the parameters used in the risk calculations.
• Although desirable, there are no single sign-on requirements
• All access to the system and reports will be within the confines of the bank's global network.
• The following events must be recorded in the system audit logs:
– Report generation.
– Modification of risk calculation parameters.
• It must be possible to understand the input data that was used in calculating risk.
• The system should take appropriate steps to recover from an error if possible, but all errors should be logged.
• All user interfaces will be presented in English only.
• All reports will be presented in English only.
• All trading values and risk figures will be presented in US dollars only.
• A Simple Network Management Protocol (SNMP) trap should be sent to the bank's Central Monitoring Service in the following circumstances:
– When there is a fatal error with a system component.
– When reports have not been generated before 9am Singapore time.
• Input files used in the risk calculation process must be retained for 1 year.

   a. Find the architectural characteristics of the ticket system
   b. Write one or more scenario's for each architectural characteristic
   c. Define your architecture in one or more diagram(s). Show as much architectural important aspects as possible.
   d. Find the risks of your proposed architecture
   e. Find options to mitigate the risks you found in part d.

What to hand in?

1. A PDF for part a to e.
2. Write a readme.txt file with the following statement and sign with your name:

I hereby declare that this submission is my own original work and to the best of my knowledge it contains no materials previously published or written by another person. I am aware that submitting solutions that are not my own work will result in an NC of the course.

I am aware that I am not allowed to share solutions with other students.

I am aware that if I submit only parts of this lab that points will be subtracted.

I am aware that if my lab submission does not contain this readme.txt file that I do not get points for this lab.

[your name as signature]
